A High-Dimensional Nonparametric Multivariate Test for Mean Vector

Lan Wang, Bo Peng and Runze Li

Abstract

This work is concerned with testing the population mean vector of nonnormal high-dimensional multivariate data. Several tests for high-dimensional mean vector, based on modifying the classical Hotelling $T^2$ test, have been proposed in the literature. Despite their usefulness, they tend to have unsatisfactory power performance for heavy-tailed multivariate data, which frequently arise in genomics and quantitative finance. This paper proposes a novel high-dimensional nonparametric test for the population mean vector for a general class of multivariate distributions. With the aid of new tools in modern probability theory, we proved that the limiting null distribution of the proposed test is normal under mild conditions when $p$ is substantially larger than $n$. We further study the local power of the proposed test and compare its relative efficiency with a modified Hotelling $T^2$ test for high-dimensional data. An interesting finding is that the newly proposed test can have even more substantial power gain with large $p$ than the traditional nonparametric multivariate test does with finite fixed $p$. We study the finite sample performance of the proposed test via Monte Carlo simulations. We further illustrate its application by an empirical analysis of a genomics data set.

KEY WORDS: Asymptotic relative efficiency; High dimensional multivariate data; Hotelling $T^2$ test; Nonparametric multivariate test.

1 Introduction

Let $X_1, \ldots, X_n$ be independent and identically distributed (iid) $p$-dimensional random vectors from the model $X_i = \mu + \epsilon_i$, where $\epsilon_i$ is the random error to be specified later. In this paper, we consider a novel nonparametric procedure for testing the hypothesis

$$H_0 : \mu = 0 \quad \text{versus} \quad H_1 : \mu \neq 0,$$

when $p$ is potentially much larger than $n$. Here and throughout this paper, $p$ stands for the number of variables (or features) of the data, and $n$ for the sample size.

The above testing problem is motivated by recent advances in genomics. There is growing evidence that most biological processes involve the regulation of multiple genes; and that analysis focusing on individual genes often suffer from low power to detect important genetic variation and poor reproducibility (Vo et al., 2007). As a result, increasing attention has been focused on the analysis of gene sets/pathways, which are groups of genes sharing common biological functions, chromosomal locations or regulations. In some important applications, the problem of evaluating whether a group of genes are differentially expressed can be formulated as the hypothesis in (1), where $X_i$ represents a vector of summary statistics computed on each of the $p$ genes, such as the log-intensity ratios of the red over green channels; or the log ratios of the gene expression levels between control and treatment chips (or before and after drug treatment). For example, the data set we analyzed in Section 3.2 contains microarray measurements from diabetic patients before and after insulin treatment (Wu et al., 2007, 2011).

Testing the hypothesis in (1) becomes very challenging for high-dimensional data. The traditional Hotelling’s $T^2$ test is not well defined as the inverse of sample covariance matrix may not exist when $p$ is larger than $n$. It has been observed in Bai and Saranadasa (1996) that the power of the Hotelling’s $T^2$ test can be adversely affected even when $p < n$, if the sample covariance matrix is nearly singular, see also Pan and Zhou (2011). Recently, there has been great interest in extending Hotelling’s test to the $p > n$ setting, see Bai and Saranadasa (1996, $p/n \to c \in (0, 1)$), Srivastava and Du (2008, $n = O(p^\delta)$ for some $1/2 < \delta \leq 1$), Srivastava (2009, $n = O(p^\delta)$ for some $0 < \delta \leq 1$), Lee et al. (2012, $p/n \to c > 0$), Srivastava et al. (2013, $n = O(p^\delta)$, $\delta > 1/2$), Chen and Qin (2010, $\text{Tr}(\Sigma^4) = o(\text{Tr}^2(\Sigma^2))$). Thulin (2014) proposed a more computing-intensive extension by combining Hotelling’s tests from a large
number of lower-dimensional random subspaces. A shared drawback of the aforementioned tests is that they tend to have unsatisfactory power performance when the multivariate distribution is heavy-tailed and is very sensitive to outlying observations.

In many microarray experiments, most genes are expressed at very low levels, few genes are expressed at high levels. The distribution of intensities tends to be nonnormal even after log transformation, regardless of the normalization methods (e.g., Purdom and Holmes, 2005). For the data example in Section 3.2, it is observed that the marginal distributions of the microarray expressions are nonnormal and have heavy tails based on values of their marginal kurtosises. Furthermore, in microarray experiments, outliers frequently arise due to the array chip artifacts such as uneven spray of reagents within arrays and other reasons. This motivates us to develop a nonparametric test for high-dimensional population mean vector or the location parameter without the multivariate normality assumption.

We propose a new test for hypothesis (1) based on spatial signs of the observations, and further study its asymptotic theory. Comparing with the extensions of Hotelling’s $T^2$ test (Chen and Qin, 2010), the theory for the nonparametric test with $p > n$ is considerably more challenging. To derive the asymptotic theory, we employ new probability tools on the concentration properties of certain quadratic forms, which may be of independent interest and have potential applications in developing the theory for other related high-dimensional nonparametric procedures. The proposed nonparametric test has several appealing properties. First it is directly applicable for the setting with $p > n$, and it is computationally simple. Second, the new test is shown to lose little efficiency when the underlying data are multivariate normal and to have potentially significant efficiency gain for heavy-tailed multivariate distributions. This is verified by deriving its asymptotic relative efficiency. From our Monte Carlo simulation, significant efficiency gain can be achieved at small or moderate sample size.

Nonparametric statistical procedures have been explored little in the high dimensional setting. An open question is whether their power advantage continues to hold (and if hold, to what extent) in high dimension. This work takes a substantial step towards understanding the merits of nonparametric procedures when $p > n$ by providing both theoretical justification and numerical evidence. Our theoretical analysis reveals a striking phenomenon: the efficiency gain of the new nonparametric test in the high-dimensional setting can be more substantial comparing with the well known traditional nonparametric tests efficiency gain in
the “classical” framework where \( p \) is fixed and \( n \) goes to infinity. For example, consider the \( p \)-dimensional multivariate \( t \)-distribution with 3 degrees of freedom, which is heavy-tailed. For this distribution, it is well known that the asymptotic relative efficiency of the spatial sign test versus Hotelling’s \( T^2 \) test is 1.9 for \( p = 1 \), 2.02 for \( p = 3 \), and 2.09 for \( p = 10 \). This implies an increasing trend as the dimension \( p \) increases. The theory established in this paper suggests that when \( p > n \), the asymptotic relative efficiency of the proposed new nonparametric test versus Chen and Qin’s extension of Hotelling’s \( T^2 \) test is about 2.54. This result provides strong support for the usefulness of nonparametric tests in high-dimensional problems.

It is worth noting that we do not impose structural constraints, such as sparsity, on the alternative hypothesis. Hence, it allows for a dense alternative, where many components of the vector contribute to the signal. In fact, this is one of the main motivations for gene set analysis. For many complex diseases, such as depression and diabetes, evidence from medical literature suggests that many of the genes from a biological pathway contribute small signals which are hard to detect individually. Cook et al. (2012) discussed other applications of similar nature, where sparsity may not be the reality. In the simulations, we demonstrated that the test based on marginal \( p \) values with Bonferroni or FDR correction may have low power to detect the global signal. On the other hand, in some other applications involving high-dimensional testing, there may be reasons to believe the alternative is sparse, for which case the existing tests can be further tuned to increase the power performance, see the recent work by Hall and Jin (2010), Zhong, Chen and Xu (2013) and Cai, Liu and Xia (2014), among others. It is noted that these tests use sample means as basic building blocks and hence are expected to suffer from power loss for heavy-tailed multivariate data. The new test we propose has the potential to be extended to the sparse alternative setting with the promise of improved power performance.

We introduce the high-dimensional nonparametric test in Section 2.1. We derive its limiting null distribution under a set of weak conditions in Section 2.2, and investigate its power performance under local alternatives and study the asymptotic relative efficiency in Section 2.3, some important extensions are discussed in Section 2.4. We conduct Monte Carlo simulations and analyze the gene sets from a genomics study in Section 3. Section 4 concludes the paper and discusses relevant issues. Technical proofs are given in the Appendix. The Supplemental Material include additional technical and numerical results.
2 A high-dimensional nonparametric test

We first focus on the case that the random vector $X_i$ follows an elliptical distribution. Extensions to beyond the elliptical distribution family are discussed in Section 2.4.

The class of elliptical distributions encompasses many useful non-Gaussian multivariate distributions such as multivariate $t$ distribution, multivariate logistic distribution, Kotz-type multivariate distribution, Pearson II type multivariate distribution and many others. The family of elliptical distributions is well studied in the statistical literature (e.g., Fang, Kotz and Ng, 1990). Recently, this family becomes important for modeling finance data (McNeil, Frey and Embrechts, 2005) due to its potential to accommodate tail dependence (the phenomenon of simultaneous extremes), which is important in quantitative finance but is not allowed by the multivariate normal distribution (Schmidt, 2002).

An elliptically distributed random vector $X_i$ has the following convenient stochastic representation:

$$X_i = \mu + \epsilon_i, \quad \text{and} \quad \epsilon_i = \Gamma R_i U_i,$$  

where $\Gamma$ is a $p \times p$ matrix, $U_i$ is a random vector uniformly distributed on the unit sphere in $\mathbb{R}^p$, and $R_i$ is a nonnegative random variable independent of $U_i$. The distribution of $X_i$ depends on $\Gamma$ only through $\Gamma \Gamma^T$ (Fang, Kotz and Ng, 1989). Thus, we denote $\Omega = \Gamma \Gamma^T$ for easy future reference. An important special case of (2) is the multivariate normal distribution with mean $\mu$ and covariance matrix $\Sigma$, for which $R_i^2$ has a chi-square distribution with $p$ degrees of freedom and $\Omega = \Sigma$. In general, $X_i$’s covariance matrix $\Sigma$ is related to $\Omega$ by $\Sigma = p^{-1} E(R_i^2) \Omega$.

2.1 The test statistic

Our test statistic $T_n$ is based on the spatial sign function of the observed data. The spatial sign function of $X_i$ is defined as $Z_i = \frac{X_i}{\|X_i\|}$ if $X_i \neq 0$; and $Z_i = 0$ if $X_i = 0$, where $\|X_i\|$ denotes the $L_2$ norm of $X_i$. The spatial sign vector is simply the unit vector in the direction of $X_i$. In the univariate case, it reduces to the familiar sign function.
We propose the following new nonparametric test statistics:

\[ T_n = \sum_{i=1}^{n} \sum_{j=1}^{i-1} Z_i^T Z_j, \]  

which indeed is a \( U \)-statistic. Under \( H_0 \), \( E(Z_i) = 0 \) which implies \( E(T_n) = 0 \). The above test statistic has an intuitive connection with the work of Bai and Saranadasa (1996) and Chen and Qin (2010), particularly the latter one. To see this, we note that the test statistic of Bai and Saranadasa (1996) for testing (1) is based on \( \| \bar{X} \|^2 \), while the one of Chen and Qin (2010) is based on \( \sum_{i=1}^{n} \sum_{j=1, j \neq i}^{n} X_i^T X_j \). By removing the diagonal elements in the statistic of Bai and Saranadasa (1996), Chen and Qin (2010) was able to considerably relax the restrictive condition on \( p \) and \( n \). In this spirit, we also dismiss the diagonal elements in defining \( T_n \). Our test statistic hence can be deemed as a nonparametric extension of Chen and Qin (2010).

From another perspective, the new test generalizes the multivariate spatial sign test (e.g., Brown, 1983; Chaudhuri, 1992; Möttönen and Oja, 1995) to the high-dimensional setting. In the classical setting of \( p < n \), Möttönen, Oja and Tienari (1997) derived the asymptotic relative efficiency (ARE) of the spatial sign test versus Hotelling’s \( T^2 \) test and established its theoretical advantage for heavy-tailed distributions. For example, when the underlying distribution is a 10-dimensional \( t \) distribution with \( \nu \) degrees of freedom, the ARE of the spatial sign test versus the Hotelling’s \( T^2 \) test is 2.42 when \( \nu = 3 \), and is 0.95 when \( \nu = \infty \) (multivariate normality). However, similarly as Hotelling’s \( T^2 \) test, the multivariate spatial sign test is not defined when \( p > n \). It is an open question whether we can modify it in a way such that its efficiency advantage can be preserved in the high-dimensional setting. This paper provides an affirmative answer.

**Remark 1.** It is interesting to compare with Bai and Saranadasa (1996) and Chen and Qin (2010), both of which adopt a factor model structure and a type of pseudo-independence assumption. It is noted that their model assumption excludes some commonly-used multivariate distributions such as the multivariate \( t \) distribution. However, we can show that Chen and Qin’s test remain valid for the multivariate \( t \) distribution (see the Supplementary Material); but could suffer from substantial power loss. In Section 2.4, we also extend the new test to some important models in the Chen and Qin’s class.
2.2 The limiting null distribution

Despite the simple form of $T_n$, deriving its asymptotic distribution when $p>n$ is by no means straightforward. As for any other high-dimensional inference, the most challenging issue lies in characterizing the underlying conditions for the asymptotic theory. In Bai and Saranadasa (1996) and Chen and Qin (2010), the key condition is stated through the behavior of the population covariance matrix $\Sigma = \text{Cov}(X_i)$. In Bai and Saranadasa (1996), it is assumed that $\lambda_{\text{max}}(\Sigma) = o\{\sqrt{\text{Tr}(\Sigma^2)}\}$, where $\lambda_{\text{max}}(\cdot)$ denotes the largest eigenvalue of a matrix and $\text{Tr}(\cdot)$ denotes the trace. In Chen and Qin (2010), it is assumed that $\text{Tr}(\Sigma^4) = o\{\text{Tr}(\Sigma^2)\}$, which is satisfied under quite relaxed conditions on the eigenvalues of $\Sigma$. For the nonparametric test $T_n$, it is desirable to characterize the underlying conditions in a similar fashion. However, this is challenging as the building blocks of $T_n$ are the transformations $Z_i$’s, which are not directly related to $\Sigma$.

In deriving the asymptotic properties of $T_n$, moment conditions directly related to $Z_i$’s naturally arise. Lemma 2.1 below plays an important role in this paper. It establishes some of the key properties of the moments of $Z_i$’s under a set of relaxed conditions on $\Sigma$. More specifically, we impose the following two conditions:

(C1) $\text{Tr}(\Sigma^4) = o\{\text{Tr}(\Sigma^2)\}$.

(C2) $\frac{\text{Tr}^4(\Sigma)}{\text{Tr}^2(\Sigma^2)} \exp\left\{-\frac{\text{Tr}(\Sigma)}{128p\lambda_{\text{max}}(\Sigma)}\right\} = o(1)$.

**Lemma 2.1** Suppose that conditions (C1) and (C2) hold. Let $B = E\left(\frac{\epsilon_i\epsilon_i^T}{\|\epsilon_i\|^2}\right)$. Then under $H_0$,

\[
E\{(Z_1^T Z_2)^4\} = O(1)\left(E^2\{(Z_1^T Z_2)^2\}\right), \quad (4)
\]
\[
E\{(Z_1^T B Z_1)^2\} = O(1)\left(E^2(Z_1^T B Z_1)\right), \quad (5)
\]
\[
E\{(Z_1^T B Z_2)^2\} = o(1)\left(E^2(Z_1^T B Z_1)\right). \quad (6)
\]

The above result is established by using a recent probability tool developed by El Karoui (2009) on the concentration inequality for the quadratic form of a random vector that has a uniform distribution on the unit sphere of $\mathbb{R}^p$.

Some intuition on $T_n$’s asymptotic behavior under $H_0$ can be gained by observing its first two moments. First, it is evident that $E(T_n) = 0$. To calculate its variance, we write
\[ T_n = \sum_{i=2}^{n} Y_i, \text{ where } Y_i = \sum_{j=1}^{i-1} Z_i^T Z_j. \] It follows from direct calculation that

\[
E(Y_i^2) = \sum_{j=1}^{i-1} \sum_{k=1}^{i-1} E(Z_i^T Z_j Z_i^T Z_k) = \sum_{j=1}^{i-1} E((Z_i^T Z_j)^2) \]

\[ = (i-1) \operatorname{Tr}(E(Z_1 Z_1^T)E(Z_2 Z_2^T)) = (i-1) \operatorname{Tr}(B^2), \]

where \( B \) is defined in Lemma 2.1. Hence, \( \operatorname{Var}(T_n) = \frac{n(n-1)}{2} \operatorname{Tr}(B^2). \) Although \( T_n \) has a \( U \)-statistics structure, the classical central limit theorem for \( U \)-statistics does not apply because the dimension \( p \) may depend on the sample size \( n \). By applying Lemma 2.1 and exploring the martingale structure of \( T_n \), we can establish the asymptotic normality of \( \frac{T_n}{\sqrt{\operatorname{Var}(T_n)}} \). The limiting null distribution of \( T_n \) is given in the following theorem.

**Theorem 2.2** Assume conditions (C1) and (C2) hold. Then under \( H_0 \), as \( n, p \to \infty \),

\[
\frac{T_n}{\sqrt{n(n-1) \operatorname{Tr}(B^2)}} \to N(0,1) \text{ in distribution.}
\]

**Remark 2.** Condition (C1) holds trivially if all eigenvalues of \( \Sigma \) are bounded away from 0 and \( \infty \). It is noted that the bounded eigenvalues assumption is commonly adopted in the literature of estimating high-dimensional covariance matrices (e.g., Bickel and Levina, 2008). It has also been shown that (C1) holds under some general conditions if some of the eigenvalues are unbounded (Chen and Qin, 2010).

**Remark 3.** Condition (C2) is new but quite relaxed. In particular, it is generally weaker than those conditions in the literature which explicitly imposed a relationship between \( n \) and \( p \) such as \( p = o(n^2) \). Condition (C2) holds if all eigenvalues of \( \Sigma \) are bounded away from 0 and \( \infty \). It also permits the eigenvalues to be unbounded as the exponential term is expected to converge to zero quickly if \( \frac{\operatorname{Tr}(\Sigma)}{\sqrt{p \lambda_{\max}(\Sigma)}} \) diverges to \( \infty \). To see this, let \( \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_p \) be ordered eigenvalues of \( \Sigma \). Assume that as \( p \to \infty \), \( k_1 \) eigenvalues converge to 0; \( k_2 \) eigenvalues diverge to \( \infty \); and \( p - k_1 - k_2 \) eigenvalues remain bounded with lower bound \( c_1 > 0 \) and upper bound \( c_2 < \infty \). Then

\[
\frac{\operatorname{Tr}(\Sigma)}{\sqrt{p \lambda_{\max}(\Sigma)}} \geq \frac{k_1 \lambda_1 + c_1(p - k_1 - k_2) + k_2 \lambda_{p-k_2+1}}{\sqrt{p \lambda_p}},
\]

\[
\frac{\operatorname{Tr}^2(\Sigma)}{\operatorname{Tr}(\Sigma^2)} \leq \frac{k_2^2 \lambda_p^2 + (p - k_2)^2 c_2^2 + 2k_2(p - k_2)c_2 \lambda_p}{k_1 \lambda_1^2 + (p - k_1) c_1^2}.
\]
Assume $\lambda_1 = p^{-b_1}$ and $\lambda_p = p^{b_2}$ for $b_1 > 0, b_2 > 0$. If both $k_1$ and $k_2$ are bounded, then it is easy to see that condition (C2) is satisfied if $b_2 < \frac{1}{2}$. It is noted that (C2) can still hold under some extra conditions on the rate of $\lambda_1$ and $\lambda_p$ even if both $k_1$ and $K_2$ diverge to infinity at appropriate rate.

**Remark 4.** To apply $T_n$ in practice, we need an estimator of $\text{Tr}(B^2)$. Following Chen and Qin (2010), we may estimate $\text{Tr}(B^2)$ using the cross-validation approach as follows:

\[
\hat{\text{Tr}}(B^2) = \{n(n-1)\}^{-1} \text{Tr} \left\{ \sum_{1 \leq j \neq k \leq n} (Z_j - \overline{Z}_{(j,k)})Z_j^T(Z_k - \overline{Z}_{(j,k)})Z_k^T \right\},
\]

where $\overline{Z}_{(j,k)}$ is the sample mean after excluding $Z_j$ and $Z_k$. It is noteworthy that the estimator in Chen and Qin can be computationally intensive for large $p$ as each term inside the U-statistic involves multiplying high-dimensional matrices. In contrast, the computational burden of the estimator in (7) can be substantially reduced by observing that $\|Z_j\|^2 = 1$.

Let $Z^* = (n-2)^{-1} \sum_{m=1}^{n} Z_m$. In the Appendix, it is derived that

\[
\hat{\text{Tr}}(B^2) = -\frac{n}{(n-2)^2} + \frac{(n-1)}{n(n-2)} \text{Tr} \left\{ \left( \sum_{j=1}^{n} Z_j Z_j^T \right)^2 \right\} + \frac{1-2n}{n(n-1)} Z^T \left( \sum_{j=1}^{n} Z_j Z_j^T \right) Z^*
\]

\[+ \frac{2}{n} \|Z^*\|^2 + \frac{(n-2)^2}{n(n-1)} \|Z^*\|^4.\]

In Figure 1(a), we plot the empirical distribution of $\sqrt{n(n-1)} \hat{\text{Tr}}(B^2)$ and compare it with the $N(0,1)$ density curve for $n = 50, p = 1000$, where the data are generated from the $\mathcal{N}_p(0, \Sigma)$ distribution with the $(i,j)$th entry of $\Sigma$ equal to $0.8|\delta[i-j]|$. The two curves are very close to each other, which suggests that the standard normal distribution provides a satisfactory approximation of the null distribution.

### 2.3 Local power analysis

We now turn our attention to the power analysis of $T_n$ under contiguous sequences of alternative hypotheses. This analysis enables us to further investigate the asymptotic relative efficiency of $T_n$ with respect to Chen and Qin’s test (referred to as CQ test in the sequel).
Figure 1: Comparing the empirical distribution of the new test with the theoretical distribution ($n = 50$, $p = 1000$)

Some interesting findings are revealed, which suggests promising efficiency gain of the new test for heavy-tailed multivariate distributions in the high-dimensional setting.

For the local power analysis, we impose the following additional conditions.

(C3) $\exp \left( -\frac{\text{Tr}^2(\Sigma)}{256p\lambda_{\max}(\Sigma)} \right) = o\left( \min\left( \frac{\lambda_{\max}(\Sigma)}{\text{Tr}(\Sigma)}, \frac{\lambda_{\min}(\Sigma)}{\lambda_{\max}(\Sigma)} \right) \right)$.

(C4) $\lambda_{\max}(\Sigma) = o(\text{Tr}(\Sigma))$.

(C5) $\|\mu\|^2 E(\|\epsilon\|^{-2}) = o\left( \min\left( \frac{\text{Tr}(\Sigma)^2}{\lambda_{\max}(\Sigma)\text{Tr}(\Sigma)}, \frac{1}{\lambda_{\min}(\Sigma)} n^{-1/2} \frac{\text{Tr}^{1/2}(\Sigma^2)}{\text{Tr}(\Sigma)} \right) \right)$.

(C6) For some $0 < \delta < 1$, $\|\mu\|^2 E(\|\epsilon\|^{-2-2\delta}) = o\left( E^2(\|\epsilon\|^{-1}) \right)$.

Remark 5. Conditions (C3) and (C4) are concerned with the properties of the population covariance matrix $\Sigma$. These two conditions are relatively weak. In particular, they are satisfied when the eigenvalues of $\Sigma$ are bounded away from 0 and $\infty$. Conditions (C5) and (C6) can be viewed as high-dimensional local-alternative statements for $p > n$. To gain some insight into the local alternative, we consider the case the eigenvalues of $\Sigma$ are bounded away from 0 and $\infty$, then the right-hand side of (C5) is $o\left( n^{-1/2} p^{-1/2} \right)$. For $p$-dimensional spherical $t$-distribution with $\nu$ degrees of freedom, $\frac{p}{\|\epsilon\|^2} \sim F(\nu, p)$. It is easy to show that $E(\|\epsilon\|^{-2}) = \frac{1}{p-2}$. A slightly more involved calculation based on the properties of $F$-distribution reveals that $E(\|\epsilon\|^{-1}) = O(p^{-1/2})$ and $E(\|\epsilon\|^{-2-2\delta}) = O(p^{-1-\delta})$. Then the conditions in (C4) and (C5) amount to $\|\mu\|^2 = o\left( n^{-1/2} p^{1/2} \right)$ and $\|\mu\|^{2\delta} = o\left( p^\delta \right)$ for some $0 < \delta < 1$. If $\delta = 1/2$, then the condition further reduces to $\|\mu\| = o\left( n^{-1/4} p^{1/4} \right)$. If we consider the local alternatives such that all components of $\mu$ are equal to $\kappa$, then we
have \( \kappa = o(n^{-1/4}p^{-1/4}) \), which when \( p > n \) is of smaller order of \( n^{-1/2} \), the usual local alternative rate for Hotelling’s test with fixed dimension. The faster rate of local alternative can be viewed as a blessing of high dimensionality, where more information can be gained to distinguish subtle deviation from the null hypothesis.

**Theorem 2.3** Assume conditions (C1)-(C6) hold. Letting \( A = E\left\{ \frac{1}{\|\epsilon\|} (I_p - \frac{\epsilon\epsilon^T}{\|\epsilon\|^2}) \right\} \). Then as \( n, p \to \infty \),

\[
\frac{T_n - \frac{n(n-1)}{2} \mu I_p}{\sqrt{\frac{n}{n-1} \text{Tr}(B^2)}} \to N(0,1) \text{ in distribution.}
\]

Theorem 2.3 implies that under the local alternatives, the proposed level \( \alpha \) test has the local power \( \beta_n = \Phi\left( -z_\alpha + \sqrt{\frac{n}{n-1} \frac{\mu^T A^2 \mu}{\text{Tr}(B^2)}} \right) \), where \( \Phi(\cdot) \) and \( z_\alpha \) denote the cumulative distribution function and the upper \( \alpha \) quantile of the \( N(0,1) \) distribution, respectively. Let \( \eta = \frac{\mu^T A^2 \mu}{\sqrt{\text{Tr}(B^2)}} \). Figure 1(b) plots the empirical power of the proposed test as a function of \( \eta \) (for \( n = 50 \), \( p = 1000 \)) and compare it with the theoretical power given by the above formula. The data are generated from the multivariate \( t \) distribution with mean vector \( \mu \), covariance matrix \( \Sigma \) and 3 degrees of freedom, where the \( (i,j) \)th entry of \( \Sigma \) is \( 0.8|j-i| \) and \( \mu \) has all elements equal to \( \kappa \) with \( \kappa \) being chosen according to the value of \( \eta \). The plot suggests that the theoretical formula of the local power provides a reasonable approximation to the empirical power.

On the other hand, the test of CQ test has the local power \( \beta^\text{CQ}_n = \Phi\left( -z_\alpha + \frac{n\|\mu\|^2}{\sqrt{2\text{Tr}(\Sigma^2)}} \right) \). The asymptotic relative efficiency (ARE) of \( T_n \) versus the CQ test is

\[
\text{ARE}_{T_n,\text{CQ}} = \frac{\mu^T A^2 \mu}{\|\mu\|^2} \sqrt{\frac{\text{Tr}(\Sigma^2)}{\text{Tr}(B^2)}} (1 + o(1)).
\]

(9)

To appreciate the implication of the above result, we consider the asymptotic relative efficiency when the data arise from a spherical \( p \)-dimensional \( t \) distribution with \( \nu \) degrees of freedom (\( \nu > 2 \)). In this case, \( A = E[\|\epsilon\|^{-1}] p^{-1} I_p \) where \( I_p \) denotes the \( p \times p \) identity matrix, \( \text{Tr}(B^2) = p^{-1} \) and \( \text{Tr}(\Sigma^2) = p^{-1} E^2[\|\epsilon\|^2] \). Hence, \( \text{ARE}_{T_n,\text{CQ}} = \frac{p^{-2} (p-1)^2 E^2[\|\epsilon\|^{-1}] E[\|\epsilon\|^2]}{\text{Tr}(\Sigma^2)} \). For the \( t \) distribution, we have \( E[\|\epsilon\|^2] = \frac{\nu}{\nu-2} \) and \( E[\|\epsilon\|^{-1}] = \sqrt{\frac{2}{\nu} \Gamma((\nu+1)/2)} \), where \( \Gamma(t) = \int_0^\infty u^{t-1} e^{-u} du \) denotes the gamma function. For large \( p \), the asymptotic relative efficiency thus is approximately \( \text{ARE}_{T_n,\text{CQ}} \approx \frac{2}{\nu^2} \left( \frac{\Gamma((\nu+1)/2)}{\frac{1}{2} \Gamma(\nu/2)} \right)^2 \). For \( \nu = 3 \), this value is about 2.54; for \( \nu = 4 \), it is about 1.76; for \( \nu = 5 \), it is about 1.51; for \( \nu = 6 \), it is about 1.38; for \( \nu = \infty \) (corresponding to multivariate normal distribution), by noting that \( \Gamma((\nu+1)/2) \approx \Gamma(\nu/2) \sqrt{\frac{\nu}{2}} \) as \( \nu \to \infty \), we have that the ARE has limit one. Theoretically, the efficiency loss of the
new test under multivariate normality is little, but the efficiency gain can be substantial for heavy-tailed distribution. Recall that for $\nu = 3$, the ARE of the classical spatial sign test versus Hotelling’s $T^2$ is 2.02 for $p = 3$ and 2.09 for $p = 10$ in the fixed dimensional case. This suggests that nonparametric test may have more substantial power gain in the high-dimensional case.

2.4 Extensions to beyond the elliptical distribution family

In this paper, we focus on the family of elliptical distributions because its popularity and flexibility for modeling non-normal multivariate data. Our results have the potential to extend to some useful multivariate distributions beyond the family of elliptical distributions.

One such class of distributions are those generated from the symmetric independent component models (e.g., Ilmonen and Paindaveine, 2011). That is,

$$X_i = \mu + \Gamma Z_i,$$

where $\Gamma$ is a full rank $p \times p$ positive definite matrix; $Z_i = (Z_{i1}, \ldots, Z_{ip})'$ has independent components $Z_{ij}$ and $Z_{ij}$ is symmetric about zero. The independent components model assumes that the observed random vector can be written as linear combinations of independent random variables. This model has received broad attentions in signal processing and machine learning (Hyvärinen, Karhunen and Oja, 2001). For example, independent component analysis with exponential power marginal density ($p(x) \propto \exp(-|x|^q)$ for some $q > 0$) is popular for analyzing image and sound signals. It is noted that this class of models encompass many of the practically useful distributions from Bai and Saranadasa (1996) and Chen and Qin (2010).

We assume that $Z_{ij}$ are standardized such that $Var(Z_{ij}) = 1$. Thus $Var(X_i) = \Gamma \Gamma^T$. We also assume that $Z_{ij}$ has a sub-exponential distribution with exponent $\alpha$, that is, there exist constants $a > 0$, $b > 0$ such that for all $t > 0$, $P(|Z_{ij}| \geq t^\alpha) \leq a \exp(-bt)$. If $\alpha = 1/2$, then $Z_{ij}$ is sub-gaussian. The class of sub-exponential distributions include many practically used heavy-tailed distributions. The fact that our proposed test is still valid for this class is summarized in the following theorem, whose proof is given in the Supplementary Material.

**Theorem 2.4** Assume (C1) and (C2) hold for model (10), $E(Z_{ij}^4) \leq c$ for some positive
constant $c$ for all $i, j$, and $\text{Tr}(\Sigma^2) = o(\text{Tr}^2(\Sigma))$. Then $\frac{T_n}{\sqrt{(n-1)/2} \text{Tr}(B^2)} \to N(0,1)$ in distribution under $H_0$, as $n, p \to \infty$, where $B$ has the same expression as in Lemma 2.1.

Another interesting extension of the elliptical distributions involves generating random variables from (2) but allowing $R_i$ to be negative and depend on $U_i$. This yields the so-called family of generalized elliptical distributions. The asymptotic results of this paper also hold for this class by observing that $\frac{X_i}{\|X_i\|} = \frac{U_i}{\|U_i\|}$ under $H_0$. This class of models recently caught the attentions of researchers in finance, see Branco and Dey (2001), Frahm (2004), among others. A representative example of this class is the collection of multi-tail elliptical distributions, where $R_i$ is a positive random variable whose tail parameter depends on $\Gamma U_i$ (e.g., Kring et al, 2009; Rachev et al, 2011). The multi-tail elliptical distributions are particularly useful for modeling asset returns in finance.

Not surprisingly, generalizations to other multivariate distributions are possible although a case-by-case consideration may be needed. Particularly, the requirement that the $U_i$ in (2) is uniformly distributed on the $L_2$ sphere can be relaxed. For example, one possible extension is to allow $U_i$ to be from the class of distributions discussed in Gupta and Song (1997) and Szablowski (1998). Concentration inequalities similar to that given in Lemma A.2, which plays an important role in the proof, can be obtained for random vectors that satisfy certain concentration of measure properties (El Karoui, 2009).

3 Numerical studies

3.1 Monte Carlo simulations

We compare the performance of the new test with four alternatives: the test of Chen and Qin (CQ test, 2010), the test of Srivastava, Katayama and Kano (SKK test, 2013), the test based on multiple comparison with Bonferroni correction (BF test), and the test based on multiple comparison with FDR control (FDR test, Benjamini and Hochberg, 1995). The SKK test is constructed using the inverse of the diagonalized version of the sample covariance matrix and is computationally attractive as it involves a simple estimator for the asymptotic covariance. The BF test controls the family error rate at 0.05 and the FDR test controls the false discovery rate at 0.05. Both the BF test and FDR test are computed using the p-values from the $t$ tests for the marginal hypotheses and reject $H_0$ if at least one marginal test is signifi-
Example 1. In this example, random data were generated from $N_p(\mu, \Sigma)$. We consider three different choices for $\mu$ and three different choices for $\Sigma = (\sigma_{ij})$.

The three choices for $\mu$ are: (1) the null hypothesis $\mu_0 = (0, \ldots, 0)^T$; (2) the alternative $\mu_1 = (0.25, 0.25, \ldots, 0.25)^T$; and (3) the alternative $\mu_2 = (\mu_{21}, \ldots, \mu_{2p})^T$ with $\mu_{21} = \ldots = \mu_{2p_3} = 0$, $\mu_{2(p_3+1)} = \ldots = \mu_{2(p_3+6)} = 0.25$ and $\mu_{2(2p_3+1)} = \ldots = \mu_{2p} = -0.25$. The three choices for $\Sigma$ are: (1) $\sigma_{ii} = 1$ and $\sigma_{ij} = 0.2$ ($i \neq j$); (2) $\sigma_{ij} = 0.8^{|i-j|}$; and (3) $\Sigma = DRD$, where $D = \text{diag}(d_1, \ldots, d_p)$ with $d_i = 2 + (p - i + 1)/p$, $R = (r_{ij})$ with $r_{ii} = 1$ and $r_{ij} = (-1)^{i+j}(0.2)^{|i-j|^{0.1}}$ for $i \neq j$. In the tables, we denote these three choices for $\Sigma$ by $\Sigma_1$, $\Sigma_2$ and $\Sigma_3$, respectively. It is noted that $\Sigma_3$ was considered in Srivastava, Katayama and Kano (2013).

Table 1 summarizes the simulations results for different choices of $\Sigma$, $\mu$, $n$ and $p$. We observe that the five tests have nominal levels reasonably close to 0.05, especially when $n = 50$. For the alternative $\mu_1$, the performance of the new test is very close to that of the CQ test and the SKK test, which are significantly better than the BF test and the FDR test. The latter two tests have especially low power when $n = 20$. For the alternative $\mu_2$, we first note that the BF test and the FRD test perform fine for $\Sigma_1$ when $n = 50$ but has significantly lower power in all other settings. We also observe that the new test, the CQ test and the SKK test perform similarly for $\Sigma_3$; the new test has somewhat better performance for $\Sigma_1$; and the SKK test has somewhat better performance for $\Sigma_2$ for $p = 1000$.

Example 2. We simulate $X_i$ from a $p$-variate $t$ distribution with mean vector $\mu$, covariance matrix $\Sigma$ and 3 degrees of freedom. The choices of $\mu$ and $\Sigma$ are set to be the same as those in Example 1. The distribution is heavy-tailed in this example.

We summarize the simulation results in Table 2. Both the new test and the CQ test have empirical levels close to 0.05 under the null hypothesis $\mu_0$ while the other three tests tend to be conservative. In this example, the BF test and FDR test perform unsatisfactorily under the alternatives $\mu_1$ and $\mu_2$. It is observed that the new test has the best power performance in all settings; which is often substantially higher than (sometimes more than twofold) the
second best performed test (the CQ test in this example). For example, the new test (and the CQ test) has power 0.83 (and 0.36) for the setting with $\mu = \mu_2$, $\Sigma = \Sigma_1$, $n = 20$ and $p = 2000$; 0.98 (and 0.47) for the setting with $\mu = \mu_1$, $\Sigma = \Sigma_2$, $n = 50$ and $p = 1000$; 0.88 (and 0.51) for the setting with $\mu = \mu_1$, $\Sigma = \Sigma_3$, $n = 20$ and $p = 2000$.

[Table 2 is about here]

**Example 3.** We simulate $X_i$ from a scale mixture of two multivariate normal distributions $0.9 \ast N_p(\mu, \Sigma) + 0.1 \ast N_p(\mu, 9\Sigma)$, where we consider the same choices of $\mu$ and $\Sigma$ as in Example 1. The distribution in this example also has heavy tails.

We summarize the simulation results in Table 3. Similarly as in Example 2, the new test significantly outperforms the four contending approaches. For example, the new test (and the CQ test) has power 0.88 (and 0.49) for the setting with $\mu = \mu_2$, $\Sigma = \Sigma_1$, $n = 20$ and $p = 2000$; 0.80 (and 0.42) for the setting with $\mu = \mu_2$, $\Sigma = \Sigma_2$, $n = 50$ and $p = 1000$; 0.91 (and 0.70) for the setting with $\mu = \mu_1$, $\Sigma = \Sigma_3$, $n = 20$ and $p = 2000$.

[Table 3 is about here]

### 3.2 An application

Type 2 diabetes is one of the most common chronic diseases. Insulin resistance in skeletal muscle, which is the major site of glucose disposal, is a prominent feature of Type 2 diabetes. To study insulins ability to regulate gene expression, an experiment performed microarray analysis using the Affymetrix Hu95A chip of human skeletal muscle biopsies from 15 diabetic patients both before and after insulin treatment (Wu et al., 2007). The gene expression alterations are promising to provide insights on new therapeutic targets for the treatment of this common disease. Hence, we are interested in testing the hypothesis in (1), where $\mu$ represents the average change of the gene expression level due to the treatment.

The underlying genetics of Type 2 diabetes were recognized to be very complex. It is believed that Type 2 diabetes is resulted from interactions between many genetic factors and the environment. The data were normalized by quantile normalization. When multiple probes are associated with the same gene, their expression values are consolidated by taking the average. In our analysis, we considered 2519 curated gene sets.
The gene sets we used are from the C2 collection of the GSEA online pathway databases (http://www.broadinstitute.org/gsea/msigdb/collection_details.jsp#C2). The largest gene set contains 1607 genes, which makes the hypothesis testing problem a high-dimensional one.

We applied both the new test and the CQ test at 5% significance level with the Bonferroni correction to control the family-wise error rate at 0.05 level. For the CQ method, 520 gene sets (20.64% of all candidates) are identified as significant; and for the new method, 954 gene sets (37.87% of all candidates) are selected as significant. We observe that the significant gene sets selected by the new test include those identified by the CQ test with only one exception (HASLINGER_B_CLL_WITH_CHROMOSOME_12_TRISOMY).

Table 4 displays the top 10 significant gene sets identified by the two tests and their corresponding test statistics values. The “NA” values in the table correspond to gene sets in the top 10 list of one test but not the other. We observe these two lists share 7 common gene sets. Among these seven gene sets, ZWANG_CLASS_2_TRANSIENTLY_INDUCED_BY_EGF, NAGASHIMA_EGF_SIGNALING_UP, AMIT_EGF_RESPONSE_60_HELA, AMIT_SERUM_RESPONSE_40_MCF10A and AMIT_SERUM_RESPONSE_60_MCF10A are known to be biologically related to insulin effect on human cells. We also observe that for 9 out of the top 10 gene sets, the new test has a smaller p-value than the CQ test does. The gene set SEMENZA_HIF1_TARGETS is only on the top ten list of the new test and was also found to be biologically related to insulin effect on human cells. Most of those significant gene sets are induced by Epidermal growth factor (EGF) or insulin-like growth factor (IGF).

[Table 4 is about here]

It is interesting to point out that exploratory analysis of the gene expression data suggests the multivariate normality assumption is questionable. In fact, we investigated each of the top 10 gene sets identified by the new test and found that the multivariate normal distribution is plausible for none of them. For example, Figure 2 displays the histogram of the marginal kurtosises of the difference of each gene expression levels (before/after the treatment) of all genes in MCCLUNG_CREB1_TARGETS_DN gene set, which was selected among the top 10 gene sets by the new method but not by the CQ method. Figure 2 clearly shows that some gene expression levels have heavy tails as their kurtosises are much larger than 3, the kurtosis of a normal distribution.

16
4 Conclusion and discussions

The paper proposes a new spatial sign based nonparametric test for testing a hypothesis about the location parameter of a high-dimensional random vector. The goal is to improve the power performance when the underlying distribution of the data deviates from multivariate normality. We investigate the asymptotic properties of the new test and compare it with alternative tests based on extending Hotelling’s $T^2$ test. A remarkable finding is the power improvement in the large $p$ setting can be more substantial than that in the classical fixed $p$ setting. The proposed test can be used as a basic building block to develop nonparametric tests in other important settings such as testing for sparse alternative or testing a hypothesis on coefficients in high-dimensional factorial designs (Zhong and Chen, 2011). A spatial sign based test was proposed for sphericity when $p = O(n^2)$ in Zou et al. (2014), and spatial sign tests were proposed for testing uniformity on the unit sphere and other related null hypotheses when $p/n \to c$ for some positive constant $c$ in Paindaveine and Verdebout (2013). The techniques related to sign tests have the potential to be used to develop the high-dimensional theory for other classical nonparametric multivariate testing procedures, such as those based on spatial sign ranks (e.g., Möttönen and Oja, 1995) and ranks (e.g., Hallin and Davy Paindaveine, 2006).

For reasons discussed in the introduction section, detecting the significance of a gene set is often of independent interest. In particular, finding significant gene sets/pathways
can improve our understanding of the biological processes associated with a specific disease. The proposed method can also be incorporated into a multi-step procedure, in combination with various gene-level testing procedures and multiple tests correction methods, to further identify a short list of top genes for the biologists. This kind of multi-step procedure is expected to have better power to identify important individual genes as the gene set acts as a dimension reduction from potentially thousands of genes.

References

Appendix: Technical proofs

Appendix 1: Some useful lemmas

We present below several useful technical lemmas, the proof for which can be found in the online supplementary material.

**Lemma A.1** Let \( U = (U_1, \ldots, U_p)^T \) be a random vector uniformly distributed on the unit sphere in \( \mathbb{R}^p \). Then

1. \( E(U) = 0 \), \( \text{Var}(U) = p^{-1}I_p \), \( E(U_j^4) = \frac{3}{p(p+2)} \), \( \forall \ j \), and \( E(U_j^2U_k^2) = \frac{1}{p(p+2)} \) for \( j \neq k \).
2. Let \( M \) be a deterministic real-valued matrix. Assume that \( \|M\|_2 \leq k \), where \( \|M\|_2 \) denotes the spectral norm of \( M \). Then, \( \forall t > 0 \), \( P\left( |U^TMU - p^{-1}\text{Tr}(M)| > t \right) \leq 2 \exp\left( -\frac{(p-1)(t-c_p)^2}{8k^2} \right) \), where \( c_p = \sqrt{\frac{8\pi k^2}{p-1}} \).

**Lemma A.2** (A concentration inequality) Assume \( W = \Gamma U \), where \( U \) is uniformly distributed on the unit sphere in \( \mathbb{R}^p \). Let \( \Omega = \Gamma \Gamma^T \) and consider the event \( A = \{ \text{Tr}(\Omega)^2 \leq \|W\|^2 \leq 3\text{Tr}(\Omega)^2 \} \). Then \( P(A) \geq 1 - c_1 \exp\left( -\frac{\text{Tr}(\Sigma)^2}{128p\lambda_{\max}(\Sigma)} \right) \), for all \( p > 1 \), where \( c_1 = 2 \exp(\pi/2) \) is a finite constant.

**Lemma A.3** For any \( p \)-dimensional vectors \( X \) and \( \mu \), we have (1) \( \frac{X - \mu}{\|X - \mu\|} - \frac{X}{\|X\|} \leq 2\frac{\|\mu\|}{\|X\|} \), and (2) \( \left\| \frac{X - \mu}{\|X - \mu\|} - \frac{X}{\|X\|} - \frac{1}{\|X\|} (I_p - \frac{XX^T}{\|X\|^2}) \mu \right\| \leq c_2 \frac{\|\mu\|^{1+\delta}}{\|X\|^{1+\delta}} \), for all \( 0 < \delta < 1 \), where \( c_2 \) is a constant that does not depend on \( X \) or \( \mu \).

**Lemma A.4** Let \( B \) be the matrix defined in Lemma 2.1. Assume condition (C3) holds, then \( \lambda_{\max}(B) \leq \frac{2\lambda_{\max}(\Sigma)}{\text{Tr}(\Sigma)} (1 + o(1)) \).

**Lemma A.5** Let \( A \) be the matrix defined in Theorem 2.3 and \( D = E\left\{ \frac{1}{\|\epsilon\|^2} \left( I_p - \frac{\epsilon_1^T}{\|\epsilon\|^2} \right) \right\} \), then \( \lambda_{\max}(A) \leq E(\|\epsilon_1\|^{-1}) \) and \( \lambda_{\max}(D) \leq E(\|\epsilon_1\|^{-2}) \). Furthermore, if conditions (C3) and (C4) hold, then \( \lambda_{\min}(A) \geq \frac{1}{\sqrt{3}} E(\|\epsilon_1\|^{-1})(1 - o(1)) \).

Appendix 2: Proof of main theorems

We use \( c \) or \( C \) to denote generic positive constants, which may vary from line to line.
Proof of Theorem 2.2. Let \( S^2_n = \text{Var}(T_n) = \frac{n(n-1)}{2} \text{Tr}(B^2) = \frac{n(n-1)}{2} E\{(Z_i^T Z_2)^2\} \). Let \( V^2_n = \sum_{i=2}^n E(Y_i^2 | Z_1, \ldots, Z_{i-1}) \) and \( Y_i = \sum_{j=1}^{i-1} Z_i^T Z_j \). To apply the martingale central limit theorem (Hall and Heyde, 1980), it is sufficient to check two conditions:

\[
S_n^{-1} \sum_{i=2}^n E(Y_i^4) \to 0 \text{ as } n, p \to \infty, \tag{A.1}
\]

\[
S_n^{-2} V_n^2 \to 1 \text{ in probability as } n, p \to \infty. \tag{A.2}
\]

To check (A.1), note that under \( H_0 \),

\[
E(Y_i^4) = E\left\{ \left( \sum_{j=1}^{i-1} Z_i^T Z_j \right)^4 \right\} = \sum_{j=1}^{i-1} E\{ (Z_i^T Z_j)^4 \} + 3 \sum_{1 \leq j, k \leq i-1 \atop j \neq k} E\{ (Z_i^T Z_j)^2 (Z_i^T Z_k)^2 \}
\]

\[
= (i-1) E\{ (Z_1^T Z_2)^4 \} + 3(i-1)(i-2) E\{ (Z_1^T Z_2)^2 (Z_1^T Z_3)^2 \}.
\]

Hence, \( \sum_{i=1}^n E(Y_i^4) \leq c \left[ n^2 E\{ (Z_1^T Z_2)^4 \} + n^3 E\{ (Z_1^T Z_2)^2 (Z_1^T Z_3)^2 \} \right] \leq cn^3 E\{ (Z_1^T Z_2)^4 \} \) by Hölder’s inequality. By Lemma 2.1, we have \( E\{ (Z_1^T Z_2)^4 \} = o\left( nE^2\{ (Z_1^T Z_2)^2 \} \right) \). Therefore, (A.1) holds.

To prove (A.2), it is sufficient to verify that \( \frac{E(V^2_n - S^2_n)}{S^2_n} \to 0 \) as \( n, p \to \infty \). We write \( V^2_n = \sum_{i=2}^n V_{ni} \), where \( V_{ni} = E(Y_i^2 | Z_1, \ldots, Z_{i-1}) \). We have

\[
V_{ni} = \sum_{j=1}^{i-1} \sum_{k=1}^{i-1} E(Z_i^T Z_j Z_i^T Z_k | Z_1, \ldots, Z_{i-1}) = \sum_{j=1}^{i-1} \sum_{k=1}^{i-1} \text{Tr}(Z_j Z_k^T B) = \sum_{j=1}^{i-1} \sum_{k=1}^{i-1} Z_j^T B Z_k
\]

\[
= 2 \sum_{1 \leq j < k \leq i-1} Z_j^T B Z_k + \sum_{j=1}^{i-1} Z_j^T B Z_j.
\]

If \( j_1 \leq k_1 \) and \( j_2 \leq k_2 \), then

\[
E(Z_{j_1}^T B Z_{k_1} Z_{j_2}^T B Z_{k_2}) = E\{ (Z_1^T B Z_1)^2 \} I\{ j_1 = k_1 = j_2 = k_2 \} + E^2(Z_1^T B Z_1) I\{ j_1 = k_1 \neq j_2 = k_2 \}
\]

\[
+ E\{ (Z_1^T B Z_2)^2 \} I\{ j_1 = j_2, k_1 = k_2, j_1 < k_1 \}.
\]
Therefore, for $i_1 \leq i_2$,

\[
E(V_{ni_1} V_{ni_2}) = 4 \sum_{1 \leq j < k \leq i_1 - 1} E\{(Z_1^T BZ_2)^2\} + \sum_{j=1}^{i_1-1} \sum_{k=1}^{i_2-1} E^2(Z_1^T BZ_1) + \sum_{j=1}^{i_1-1} [E\{(Z_1^T BZ_1)^2\} - E^2(Z_1^T BZ_1)]
\]

\[
= 2(i_1 - 1)(i_1 - 2)E\{(Z_1^T BZ_2)^2\} + (i_1 - 1)(i_2 - 1)E^2(Z_1^T BZ_1) + (i_1 - 1)Var(Z_1^T BZ_1).
\]

Consequently,

\[
E(V_n^4) = E\{(\sum_{i=2}^{n} V_{ni})^2\} = 2 \sum_{2 \leq i < j \leq n} E(V_{ni}V_{nj}) + \sum_{i=2}^{n} E(V_{ni}^2)
\]

\[
= 2 \sum_{i=2}^{n} (i - 1)(i - 2)(2n - 2i + 1)E\{(Z_1^T BZ_2)^2\} + \sum_{i=2}^{n} (i - 1)(2n - 2i + 1)Var(Z_1^T BZ_1)
\]

\[
+ \left\{n(n - 1)E(Z_1^T BZ_1)/2\right\}^2.
\]

Note that $E(Z_1^T BZ_1) = \text{Tr}(B^2)$ and $S_n^2 = \frac{n(n-1)}{2} \text{Tr}(B^2)$. Hence,

\[
E\{(V_n^2 - S_n^2)^2\} = E(V_n^4) - S_n^4
\]

\[
= 2 \sum_{i=2}^{n} (i - 1)(i - 2)(2n - 2i + 1)E\{(Z_1^T BZ_2)^2\} + \sum_{i=2}^{n} (i - 1)(2n - 2i + 1)Var(Z_1^T BZ_1)
\]

\[
\leq c\left[n^4E\{(Z_1^T BZ_2)^2\} + n^3E\{(Z_1^T BZ_1)^2\}\right].
\]

Hence, a sufficient condition for $S_n^{-4}E(V_n^2 - S_n^2)^2 \to 0$ is $\frac{n^4E\{(Z_1^T BZ_2)^2\} + n^3E\{(Z_1^T BZ_1)^2\}}{n^4E\{(Z_1^T BZ_1)^2\}} \to 0$.

This condition holds by Lemma 2.1. This finishes the proof of Theorem 2.2. □

**Proof of Theorem 2.3.** Under the local alternatives,

\[
T_n = \sum_{i=1}^{n} \sum_{j=1}^{n} \{ \frac{\epsilon_i}{\|\epsilon_i\|} + \left( \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} / \frac{\epsilon_i}{\|\epsilon_i\|} \right) \} \{ \frac{\epsilon_j}{\|\epsilon_j\|} + \left( \frac{\epsilon_j + \mu}{\|\epsilon_j + \mu\|} \right) \}
\]

\[
= T_{n1} + T_{n2} + T_{n3},
\]

23
where $T_{n1} = \sum_{i=1}^{n} \sum_{j=1}^{n} \frac{\epsilon_i^T \epsilon_j}{\|\epsilon_i\| \|\epsilon_j\|}$, $T_{n2} = \sum_{i=1}^{n} \sum_{j=1}^{n} \left( \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} - \frac{\epsilon_i}{\|\epsilon_i\|} \right) T_{i,j}$, and $T_{n3} = \sum_{i=1}^{n} \sum_{j=1}^{n} \left( \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} - \frac{\epsilon_i}{\|\epsilon_i\|} \right) T_{i,j}$. By Theorem 2.2, $T_{n1}/\sqrt{n(n-1)/2} \rightarrow N(0,1)$.

To analyze $T_{n2}$, we write $T_{n2} = T_{n21} + T_{n22}$, where $T_{n21} = \sum_{i<j} \left( \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} - \frac{\epsilon_i}{\|\epsilon_i\|} \right) T_{i,j}$ and $T_{n22} = \sum_{j<i} \left( \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} - \frac{\epsilon_i}{\|\epsilon_i\|} \right) T_{i,j}$. Note that $E(T_{n21}) = 0$, and

$$E(T_{n21}^2) = \sum_{i_1<j_1} \sum_{i_2<j_2} E\left\{ \left( \frac{\epsilon_{i_1} + \mu}{\|\epsilon_{i_1} + \mu\|} - \frac{\epsilon_{i_1}}{\|\epsilon_{i_1}\|} \right) T_{i_1,j_1} \left( \frac{\epsilon_{i_2} + \mu}{\|\epsilon_{i_2} + \mu\|} - \frac{\epsilon_{i_2}}{\|\epsilon_{i_2}\|} \right) \left( \frac{\epsilon_{i_2} + \mu}{\|\epsilon_{i_2} + \mu\|} - \frac{\epsilon_{i_2}}{\|\epsilon_{i_2}\|} \right) \right\}$$

$$= \sum_{i_1<j_1} \sum_{i_2<j_2} E\left\{ \left( \frac{\epsilon_{i_1} + \mu}{\|\epsilon_{i_1} + \mu\|} - \frac{\epsilon_{i_1}}{\|\epsilon_{i_1}\|} \right) T \left( \frac{\epsilon_{i_2} + \mu}{\|\epsilon_{i_2} + \mu\|} - \frac{\epsilon_{i_2}}{\|\epsilon_{i_2}\|} \right) \right\}$$

$$\leq \lambda_{\max}(B) \sum_{i_1<j_1} \sum_{i_2<j_2} E\left\{ \frac{4 \|\mu\|^2}{\|\epsilon_{i_1}\| \|\epsilon_{i_2}\|} \right\}$$

$$\leq 8 \frac{\lambda_{\max}(\Sigma)}{\text{Tr}(\Sigma)} (1 + o(1)) \|\mu\|^2 \left\{ \sum_{i<j} E(\|\epsilon_i\|^{-2}) + \sum_{i_1<j_1} \sum_{i_2<j_2} E^2(\|\epsilon_{i_1}\|^{-1}) \right\}$$

$$\leq O(n^3 \|\mu\|^2) \frac{\lambda_{\max}(\Sigma)}{\text{Tr}(\Sigma)} E(\|\epsilon\|^2),$$

where the first inequality uses Lemma A.3, and the second inequality uses Lemma A.4. In the derivation in Lemma 2.1, we derived that $\text{Tr}(B^2) \geq \frac{4}{9} \frac{\text{Tr}(\Sigma^2)}{\text{Tr}(\Sigma)} (1 - o(1))$. Hence, it follows by condition (C5) that

$$\frac{E(T_{n21}^2)}{n(n-1)/2 \text{Tr}(B^2)} \leq O(n \|\mu\|^2) \frac{\lambda_{\max}(\Sigma) \text{Tr}(\Sigma)}{\text{Tr}(\Sigma^2)} E(\|\epsilon\|^2) = o(1).$$

This implies $T_{n21}/\sqrt{n(n-1)/2 \text{Tr}(B^2)} = o_p(1)$. Similarly, $T_{n22}/\sqrt{n(n-1)/2 \text{Tr}(B^2)} = o_p(1)$.

Finally, we analyze $T_{n3}$. Denote

$$T_{n31} = \frac{n(n-1)}{2} E \left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right)^T E \left( \frac{\epsilon_2 + \mu}{\|\epsilon_2 + \mu\|} \right),$$

$$T_{n32} = \sum_{j \neq i} E \left( \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} \right)^T \left\{ \frac{\epsilon_j + \mu}{\|\epsilon_j + \mu\|} - \frac{\epsilon_j}{\|\epsilon_j\|} \right\} - E \left( \frac{\epsilon_j + \mu}{\|\epsilon_j + \mu\|} \right),$$

$$T_{n33} = \sum_{j<i} \left\{ \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} - \frac{\epsilon_i}{\|\epsilon_i\|} \right\} \left\{ \frac{\epsilon_j + \mu}{\|\epsilon_j + \mu\|} - \frac{\epsilon_j}{\|\epsilon_j\|} \right\}.$$
Then it follows that

\[ T_{n3} = \sum_{i=1}^{n} \sum_{j=1}^{n} \left[ E\left( \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} \right) + \left\{ \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} - \frac{\epsilon_i}{\|\epsilon_i\|} - E\left( \frac{\epsilon_i + \mu}{\|\epsilon_i + \mu\|} \right) \right\}^T \times \left[ E\left( \frac{\epsilon_j + \mu}{\|\epsilon_j + \mu\|} \right) + \left\{ \frac{\epsilon_j + \mu}{\|\epsilon_j + \mu\|} - \frac{\epsilon_j}{\|\epsilon_j\|} - E\left( \frac{\epsilon_j + \mu}{\|\epsilon_j + \mu\|} \right) \right\} \right] \]

\[ = T_{n31} + T_{n32} + T_{n33}. \]

To analyze \( T_{n31} \), by Lemma A.3 (2), we can write \( E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) = -A\mu + E(Q_1) \), where

\[ Q_1 = \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} + \frac{1}{\|\epsilon_1\|}(I_p - \frac{\epsilon_1^T \mu}{\|\epsilon_1\|^2}) \mu \]

satisfies \( E(\|Q_1\|^2) \leq c_3 \|\mu\|^{2+2\delta} E(\|\epsilon_1\|^{-2-2\delta}) \) for all \( 0 < \delta < 1 \), where \( c_3 \) is a constant that does not depend on \( \epsilon_1 \) or \( \mu \). Hence,

\[ E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right)^T E\left( \frac{\epsilon_2 + \mu}{\|\epsilon_2 + \mu\|} \right) = \mu^T A^2 \mu - \mu^T AE(Q_1) - \mu^T AE(Q_2) + E(Q_1)^T E(Q_2). \]

Note that by Lemma A.5 and condition (C6), the last three terms on the right-hand side of the above expression are bounded by

\[ 2c_3^{1/2} \|\mu\|^{1+\delta} \|\mu^T A\| \cdot E^{1/2}(\|\epsilon_1\|^{-2-2\delta}) + c_3 \|\mu\|^{2+2\delta} E(\|\epsilon_1\|^{-2-2\delta}) \]

\[ \leq c \|\mu\|^2 o(\|E(\|\epsilon_1\|^{-1})\|) = o(\mu^T A^2 \mu). \]

Therefore, \( T_{n31} = \frac{n(n-1)}{2} \mu^T A^2 \mu (1 + o(1)) \).

To evaluate \( T_{n32} \), we observe that \( E(T_{n32}) = 0 \) and that

\[ E(T_{n32}^2) = O(n^3) E\left( \frac{\epsilon_2 + \mu}{\|\epsilon_2 + \mu\|} \right)^T E\left\{ \left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} - E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) \right) \left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} - E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) \right)^T \right\} E\left( \frac{\epsilon_3 + \mu}{\|\epsilon_3 + \mu\|} \right). \]

Note that by Lemma A.3 (2),

\[ \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} - E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) = -\left\{ \frac{1}{\|\epsilon_1\|} \left( I_p - \frac{\epsilon_1^T \epsilon_1}{\|\epsilon_1\|^2} \right) - A \right\} \mu + (Q_1 - E(Q_1)). \]
Applying the above decomposition, we obtain

\[
\lambda_{\max}\left[ E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} - E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) \right) \left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} - E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) \right)^T \right] \\
\leq 2 \|\mu\|^2 \lambda_{\max}(D) + C \|\mu\|^{2+2\delta} E\left( \|\epsilon_1\|^{-2-2\delta} \right) \\
\leq 2 \|\mu\|^2 E\left( \|\epsilon_1\|^{-2} \right) + C \|\mu\|^{2+2\delta} E\left( \|\epsilon_1\|^{-2-2\delta} \right),
\]

by Lemma A.5, where \( D = E\left\{ \frac{1}{\|\epsilon_1\|^2} \left( I_p - \frac{\epsilon_1 \epsilon_1^T}{\|\epsilon_1\|^2} \right) \right\} \). Therefore, by Lemma A.5, conditions (C5), (C6), and observing that \( \text{Tr}(B^2) \geq \frac{4\text{Tr}(\Sigma^2)}{9\text{Tr}(\Sigma)} (1 - o(1)) \), we have

\[
E(T_{n32}^2) \leq O(n^2) \left\{ 2 \|\mu\|^2 E\left( \|\epsilon_1\|^{-2} \right) + C \|\mu\|^{2+2\delta} E\left( \|\epsilon_1\|^{-2-2\delta} \right) \right\} \|\mu\|^2 E^2\left( \|\epsilon_1\|^{-1} \right) \\
\leq O(n^2) \|\mu\|^4 E^2\left( \|\epsilon_1\|^{-2} \right) = o(n^2\text{Tr}(B^2)).
\]

Therefore, \( T_{n32}/\sqrt{n(n-1)\text{Tr}(B^2)} = o_p(1) \).

To evaluate \( T_{n33} \), we observe that \( E(T_{n33}) = 0 \) and that

\[
\begin{align*}
E(T_{n33}^2) &= O(n^2) E\left[ \left\{ \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} - E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) \right\} \left\{ \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} - E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) \right\}^T \right] \\
&= O(n^2) \left\{ 2 \|\mu\|^2 \lambda_{\max}(D) + C \|\mu\|^{2+2\delta} E\left( \|\epsilon_1\|^{-2-2\delta} \right) \right\} \\
&\times E\left[ \left| \left| \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} - \frac{\epsilon_1}{\|\epsilon_1\|} - E\left( \frac{\epsilon_1 + \mu}{\|\epsilon_1 + \mu\|} \right) \right|^2 \right] \\
&\leq O(n^2) \left\{ 2 \|\mu\|^2 \lambda_{\max}(D) + C \|\mu\|^{2+2\delta} E\left( \|\epsilon_1\|^{-2-2\delta} \right) \right\}^2 \\
&\leq O(n^2) \|\mu\|^4 E^2\left( \|\epsilon_1\|^{-2} \right) = o(n^2\text{Tr}(B^2))
\end{align*}
\]

by Lemma A.5, conditions (C5) and (C6). Therefore, \( T_{n33}/\sqrt{n(n-1)\text{Tr}(B^2)} = o_p(1) \). Summarizing the above, \( T_{n3}/\sqrt{n(n-1)\text{Tr}(B^2)} = \frac{n(n-1)^2 \mu^T A \mu (1 + o(1))}{\sqrt{n(n-1)\text{Tr}(B^2)}} + o_p(1) \). This finishes the proof. \( \Box \)
